Abstract

This article aims to equip veterinary professionals to assist clients in the use of food puzzles for their cats as tools to support feline enrichment, physical health, and emotional wellbeing. We outline the types of food puzzles, how to introduce them to cats, and how to troubleshoot challenges with their use. Due to the paucity of evidence-based studies of food puzzles, we provide examples of the use and benefits of food puzzles from our own veterinary and behavioral practices.
Introduction

Although cats are currently the most commonly kept pet in the United States, the conditions they are kept in are perhaps the least natural to them, especially given that the domestic cat’s behavior and behavioral needs are very similar to those of their closest wild ancestor, the African wildcat. Current veterinary and cat care guidelines (e.g., American Veterinary Medical Association; Indoor Pet Initiative; American Association of Feline Practitioners) encourage keeping cats indoors for safety, health, and ecological reasons, but this recommendation, along with the concurrent misperception of cats as low-maintenance pets, means that many cats are housed in suboptimal environments. One significant influence on cats’ living conditions is how they are routinely fed. Most cats are offered food ad libitum from a bowl, are often required to share feeding areas or dishes with other cats, and have to expend little to no effort to acquire calories.

Cats are natural predators who tend to eat multiple small meals each day in nature. When able to hunt, cats make several hunting attempts each day, only approximately half of which would lead to a prey item. Indoor housing has been associated with increases in the occurrence of obesity, type 2 diabetes mellitus, joint problems, as well as chronic lower urinary tract signs. Furthermore, the risk of behavioral and mental health problems may increase with confinement. Commonly reported behavioral concerns from cat owners include aggression, attention-seeking behaviors, and stress-related behaviors such as house soiling and overgrooming. These behavior problems can lead to a weakening of the human-animal bond, and in many cases result in unwarranted euthanasia of the cat. Environmental enrichment may have some mitigating effects on these stress-related behaviors.
We propose that one approach to environmental enrichment is to take advantage of cats’
natural instinct to work for their food. In this review, we will explain what food puzzles are and
why they are a biologically relevant enrichment device for cats. We will provide an overview of
the most common types of food puzzles, how they should be used, and how to overcome any
client resistance to changing the method of food delivery to their cats. The effect of food puzzles
on cats is a relatively new area of study, so in addition to reviewing the existing empirical
evidence, we will provide case studies from our professional practices showing health and
behavioral benefits from their use. Finally, we provide tools for assessing the most appropriate
types of food puzzles for individual cats, and a user-friendly handout that practitioners can give
to their clients to get them started.

What are food puzzles?

Food puzzles were originally created to provide enrichment for captive zoo and
laboratory animals.\textsuperscript{17} They typically consist of any object that can hold food, and be manipulated
to release food when the animal interacts with it. Food puzzles may be mobile (rolled or pushed)
or stationary, and they can be used to provide either wet or dry food. They may be purchased or
homemade (see Figure 1).

Mobile food puzzles are often shaped like a ball, egg, or tube. Their rounded surfaces
make the puzzles easy for cats to roll by pushing with a paw or their nose. These puzzles
typically have one or more holes in them, and in some cases these puzzles can be adjusted to
make release of food easier or harder by changing the size or number of open spaces that can
dispense food. The current iterations of these puzzles are typically designed for use with dry food
or treats.
Stationary puzzles are typically larger, with sturdy bases, and holes, cups, or channels.

Dry food can be placed in the holes and cups, which must be fished out with a paw. Wells may be filled with wet food; the cat must lick food out of these wells, mimicking how cats use their jaw muscles to remove flesh from bone.

Homemade puzzles for dry food can be made easily by cutting holes in containers such as yogurt containers, toilet paper rolls, egg cartons, margarine tubs, or water bottles. Ice cube trays or muffin pans can be used for wet food, and yogurt lids can be placed over the individual reservoirs or cups to increase difficulty.

The benefits of using food puzzles.

Zoos and sanctuaries encounter many obstacles to providing adequate housing for felid species, which may have difficulty adjusting to captivity for several reasons. Territory and hunting opportunities are restricted, and many solitary species are housed in pairs or in groups. The parallels with domestic cat housing are numerous. Implementing enrichment by providing foraging opportunities and food puzzles offers several benefits to captive large cats, including reducing stereotypies such as pacing, improving body condition, and increasing exploratory behavior.

Current guidelines for the care and welfare of domestic cats suggest that they be allowed to express the predatory sequence to the extent possible, including active acquisition of food. Although few empirical studies of the benefits of food puzzles for companion animals have been conducted, provision of food puzzles has been shown to increase activity and reduce problematic behavior in dogs. In cats, various forms of enrichment (such as play, perches, play towers, and novel toys) have been shown to reduce stress-related symptoms, and to contribute to weight-loss. Table 1 outlines cases from our veterinary and behavioral practices that resulted
in either behavioral or health-related benefits after the implementation of food puzzles along with other forms of behavior modification. Benefits we have observed include weight-loss, decreased aggression toward humans and other cats, reduced anxiety and fear, cessation of attention-seeking behaviors, and resolution of litterbox avoidance.

Furthermore, implementing food puzzles provides few risks of decreasing welfare of cats. In one study, 85% of cats (23/27) engaged with a food puzzle without increases in aggression between group-housed cats in a shelter, suggesting few problems with implementing food puzzles in multi-cat environments. Although problem-solving to acquire food may initially frustrate some animals, presenting animals with some level of challenge that is appropriate to their natural ecology and matched to their skill level is likely to provide cognitive, physical and behavioral benefits in otherwise-enriched surroundings.

**Implementing food puzzles**

As with introduction of any new resource, successfully implementing food puzzles requires some planning. Clients should be prepared to try a few different types of food puzzles, because cats may have individual preferences for the type of puzzle or how they interact with puzzles (for example, some cats prefer mobile puzzles that can be pushed or rolled while others are more adept at stationary puzzles; some cats are more likely to use their paws to move a toy, while others may push the toy with their nose). We have provided a guide to helping clients choose a starter puzzle in Table 2. Furthermore, because implementing food puzzles offers enrichment beyond just as a means of providing food, the end goal is to have several different types of puzzles available for cats (as is recommended with other toys). The most important key to success is for clients to introduce puzzles to the cats correctly. This means setting the
difficulty level to meet the abilities of the cat, and by increasing the cat’s motivation to interact
with the puzzle as much as possible.

Initially, obtaining food from the puzzle needs to be as easy as obtaining food from the
food bowl. This means that the cat should have to do very little work for food at first. The puzzle
should be filled as much as possible, and should have several, large holes to allow food to fall
out easily. The puzzle should roll with little manipulation. For stationary puzzles, cups or
reservoirs should be overflowing (see Figure 2).

As cats initially may be resistant to working for food, particularly if they have a history
of not having to do so, the regular food dish may need to be removed when introducing food
puzzles. Because some cats may view their food container as a “safety signal,” or may be
stressed by changes in their environment, some cats prefer having the puzzle initially introduced
as a choice next to the usual feeding container at the time of feeding, and containing the cat’s
usual food. Some cats, particularly those who tend to be nervous, may prefer that the food puzzle
be placed in a quiet area where they can explore it undisturbed.

The food puzzle should be introduced when the cat is likely to be hungry. Motivation
may be increased at first by using a novel food type in the puzzle, such as treats or a dental diet.
As the cats become more adept at using the puzzle, the food can be changed to their regular diet,
or a mix of their regular dry food and treats.

For dry food puzzles, the client should place food on the floor next to and around the
puzzle and allow the cat to eat around the puzzle. Their cat may inadvertently move the puzzle
while eating, which will help them make the association between moving the puzzle and
receiving food. The owner may even gently roll or nudge the puzzle at first to maintain the cat’s
interest. Eventually, regular food dishes can be removed and the cat can receive all of his or her daily food from puzzles.

Troubleshooting potential challenges and solutions

Some clients (and cats) may be reluctant to accept introduction of food puzzles. Making food puzzles as user-friendly and convenient as possible increases the client’s likelihood of using them, and consequently improves their cat’s welfare. Our collective experience is that most, if not all cats can adjust to food puzzles, given time, patience, and proper staging of difficulty. Some common challenges to food puzzle use and how we address them in our veterinary and behavioral practices include:

The client doesn’t think their cat will use food puzzles. We have not encountered cats that could not adapt to food puzzles. Senior cats, kittens, three-legged cats, blind cats, and cats with other disabilities such as partial paralysis all have been observed to use a food puzzle of some type. Reminding the client of the cat’s natural lifestyle as a hunter who works for food may be helpful. Sharing and discussing the food puzzle handout (Supplementary material) with the client, as well as demonstrating how they work will help clients get started. Providing coaching and encouragement during the implementation process reduces the likelihood of the client concluding that their cat is unwilling or unable to work for their food.

The owner will not make or purchase food puzzles. The best way to address this is to have food puzzles available for sale in the veterinary office, or to provide referrals to local pet stores that sell food puzzles. There are also many good resources online for creating food puzzles out of recyclable materials (such as yogurt containers and plastic water bottles).
The owner does not want to prepare food puzzles daily. If the client is willing, they can acquire several food puzzles to rotate. All dry food puzzles can be prepared once a week and stored in airtight storage bins.\(^3\)

The owner is concerned about noise/nighttime activity. Stationary puzzles can be used at night, or mobile food puzzles can be confined to areas away from the bedroom.

The owner is resistant to having food scattered around the home. The cat will likely eat most of the food dispensed by the puzzle. However, food puzzles can be used in select rooms (e.g., bathroom, office, kitchen), or in more restricted areas such as bathtubs, laundry baskets, under-the-bed storage containers, or in the lids of large storage totes. The downside of restricting the area the puzzle is used in is that it makes food easier to obtain, and reduces the cat’s movement and activity, and bathtubs and containers may provide other challenges for any cat with a mobility issue (such as older, arthritic cats).

The owner has tried a food puzzle and the cat would not use it. The client should be encouraged to try again, this time empowered with more detailed instructions and specific guidance. Staff should be trained to guide clients through learning challenges. Initial difficulty of use and increasing motivation are two of the most common barriers to cats’ willingness to use food puzzles. For slow starters, placing handfuls of dry food in locations frequented by the cat (condos, window sills, beds) allows the cat the chance to discover food in novel places. These cats generally can transition from this to static puzzles located in these areas.

All cats should be monitored closely at first when introducing a food puzzle, as missing several meals could be dangerous to vulnerable cats, particularly those who are overweight or obese. If the owner is concerned, they can offer the cat a portion of their daily food in a bowl, and the rest can be foraged until the cat has adapted to the use of the puzzle. Alternatively, the
cat could be fed wet food from a dish, and dry food exclusively from puzzles. The ultimate goal should be all food from puzzles.

**Multiple cats in the home.** All cats in the home can be acclimated to food puzzles. Because cats may have individual preferences, several types of food puzzles can be distributed throughout the home, and each cat should be provided with their own puzzle. If one type of puzzle is more popular, then the owner should provide multiple puzzles of that type. This prevents cats from having to compete over food resources, and from being forced to eat in the same area, a behavior that is unnatural to solitary hunters. However, some cats are willing to use a food puzzle together (see Figure 3).  

**Presence of dogs in the home.** For homes with dogs, puzzles can be used in restricted areas (see above), or baby gates can be used to keep dogs out of certain areas of the home where the cats’ food puzzles are kept. The baby gates should be placed at a height where the cat can either jump over or crawl under, but the dog cannot. Dogs also can be taught a “leave it” verbal cue, and be provided with their own foraging toys in a separate area of the house, or if possible, outdoors.

**The cat becomes bored with the food puzzles.** Adjusting the difficulty to the ability of the cat is important. Unchallenging tasks may lead to boredom or apathy. When the cat becomes competent with a particular food puzzle, clients can maintain their cat’s interest by:

1. Trying new types of food puzzles (including different designs or materials) or changing the location the puzzle is used in.
2. Increasing the difficulty of the puzzle: owners can do this by changing the number and/or size of the holes, or by using objects that are opaque and give fewer visual cues. They also can adjust how mobile the puzzle is by using weighted puzzles, cubes, or objects that have
textured sides. Changing the substrate the puzzle is offered on (for example, carpet instead of hard flooring) can increase the challenge.

3. Placing a small puzzle inside a larger puzzle (see Figure 4).

4. Placing “dummy” objects inside the puzzle such as toy balls or mice that slow the release of food.

5. Using piñata-style puzzles that dangle or hang and require the cats to reach up to manipulate them (see Figure 5). Clients should be advised that hanging toys can present a choking hazard and should only be used with supervision.

Conclusions

Food puzzles enable cat owners to provide mental stimulation and exercise, and increase the activity of their pet cats, while taking advantage of the domestic cat’s natural inclination to work (hunt) for their food. Food puzzles are relatively easy to implement, and there are few risks associated with their use. In fact, there are likely many health and behavioral benefits from implementing food puzzles. We have provided some examples of the potential benefits of their use in concert with other behavior modifications in the retrospective case studies outlined in Table 1.

We acknowledge the limitations to the cases we provided; they are retrospective in nature, and in some cases, food puzzles were not the only intervention, so one cannot be sure of the relative effectiveness of each component of the treatment. We included these cases acknowledging that this limitation is also often found in primary care medicine, and in hopes of encouraging further research to determine the most appropriate roles of food puzzles in
promoting health and welfare for confined cats. Prospective trials are greatly needed to help determine the relative effectiveness of different approaches to environmental enrichment for confined cats. We also did not include all cases seen that involved recommendations for the use of food puzzles, although we attempted to provide a range of the types of cases that might be commonly encountered in primary care veterinary practice. Veterinary practices are often the main source of information for many pet owners, and we have provided suggestions, tools, and user-friendly information to help veterinary professionals make the recommendation of food puzzles a standard practice.

Conflict of interest statement
The authors declare no potential conflict of interest with respect to the research, authorship, and/or publication of this article.

Funding
This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. MMD was supported by an NSF GRFP fellowship.

Using Food Puzzles with Your Cat
Leticia Dantas, Mikel Delgado, Ingrid Johnson, and Tony Buffington

Food puzzles are an excellent way to increase your cat’s activity and mental health by giving them a new, more natural way to get their food by “hunting” for it. Food puzzles typically come in two styles, rolling and stationary. They can be purchased or homemade, and can be used with dry or wet food, or treats.

**Beginners** should start with clear puzzles with many openings so that cats can see, smell, and hear that there is food inside and will be rewarded with food for even gently nudging it. Puzzles should be at least one-half to three-quarters of the way full so the food easily dispenses. An almost empty puzzle can be too challenging and create frustration.

If dry food is fed, sprinkle some around the puzzle so the cat can acquire a few pieces and nudge the puzzle for more. Your cat will make the connection between moving the puzzle and obtaining food.

For **slow starters**, place small handfuls of dry food in locations frequented by the cat (condos, window sills, beds.). This allows the cat to discover food in novel places.

Gradually **increase the challenge**: use puzzles that are opaque, have fewer or smaller holes, or have unique shapes such as a cube, which makes them more challenging to manipulate.

For **stationary puzzles** begin with egg cartons, muffin pans, ice cube trays or commercially available puzzles (the Catch by Northgate, or the Tunnel Feeder by Trixie Pet). Muffin pans and ice cube trays are well-suited for use with wet food.

**Advanced foragers may also benefit from:**
- Hiding the puzzles around the house.
- Doubling up objects by filling a smaller puzzle and placing it inside a larger puzzle, so that the cat must work harder to acquire food.
- Placing a small weight or objects (such as a ping pong ball) inside the puzzle increases the challenge, by making it harder for the cat to move the puzzle, and for food to fall out.

Eventually, you can even feed your cat all of their meals from food puzzles. Food puzzles increase your cat’s exercise, allow them to use their minds to obtain food, and can provide entertainment for both you and your cat.
